Preface

It is a great pleasure to bring out the Population Projections for Nepal 2011-2031 based on the results of the National Population and Housing Census 2011 (NPHC-2011). The projection is one of the special post-census activities carried out by Central Bureau of Statistics (CBS) Nepal. The previous population projection was done in 2003 based on Population Census 2001 with joint collaboration of Ministry of Population and Environment and CBS.

This series of population projection for Nepal has given due consideration for the periodic plans of the Government of Nepal and useful denominators for national level socio-economic estimates. Based on National level, urban projections have been made for the existing 58 municipal areas. In a similar manner, projections at district level have also been made for each district at an interval of five years. In this way, the projected population has been computed at other sub-national level i.e. ecological belts, development regions and eco-development regions. By and large, this report encompasses all the projected population by sex and five year age group.

I hope this publication of population projection for 2011-2031 will be very useful in planning purpose for both government and non-government sectors. It will also serve as basic input for users engaged in research and study task. In order to make improvements of such reports in the future, I would always welcome valuable comments and suggestions from users. I would like to thank the Technical Committee Members of the NPHC-2011 for their technical input and finalizing the projection for forthcoming years. My special thanks also go to the members of Steering Committee for their direction, in-depth discussions, suggestions and approval of this projection task.

I would like to thank to the United Nations Population fund (UNFPA) for the cooperation in projection work as well as for the census activities. From my side, special thank goes to consultant and senior demographer Dr. Pushpalal Joshi for his valuable contribution in this task. Heartily thank goes to Dr. Rudra Suwal, Deputy Director General of the Bureau for his overall coordination in projection work. Director Shanker Lal Shrestha and Indra Bahadur Karki, Statistical Officer Sunil Kumar Shrestha, Statistical Assistants Bimal Bhattarai and Bishnu Raj Regmi were devoted for the projection work. They all deserve special thanks.

I would like to deserve my special thanks to Statistical Officer Yadu Nath Acharya and Computer Officer Dol Narayan Shrestha for their appreciable job on handling related software and making sub-national projections. My thanks also go to all other staffs of the Population Section and other sections of the Bureau for their support and co-operation in bringing out this projection report.

Finally, I would like to thank all those persons whose support and cooperation has contributed in completing this job successfully.

POPULATION PROJECTION
2011 - 2031

Population Projections for Nepal

2011 - 2031

1. Introduction

Population projections are extremely needed for making development plans at national and sub-national levels. In Nepal, the sub-national levels may be urban-rural, development regions, ecological zones, districts and federal areas which will come into existence after the promulgation of the new constitution.

Projections have to be made by age-sex distribution of the population in order to have projections of socioeconomic characteristics at all levels. They will be needed to get an estimate of future need of goods, services and facilities such as food, clothing, housing, water and sewage facilities, schools, hospitals and other community facilities. As such, there is no doubt that projected populations need to be accurate as far as possible. They will be accurate if data used are reliable, appropriate methodologies are used and plausible assumptions about population components are made. The components of populations are the levels of fertility, mortality and migration and their trends in future. They need to be estimated accurately as far as possible.

As the census date is June 22, 2011, the base year for the population projection is taken as 2011. Keeping in mind that the longer the period of projection, the greater the errors will be in assumptions and the lesser utilization of population projections, the final year for the projection is taken as 2031. The fertility and mortality levels for June 2011 are estimated by applying various methodologies to various available data. The effect of migration component is evaluated based on foreign born citizens and absentee population based on 2011 census. Various assumptions about the trend of fertility, mortality and migration components are made. As various combinations of assumptions about fertility, mortality and migration trends will lead to a large number of population projections, three variants of fertility, one variant of mortality and one variant of migration trend are used. Thus there are three scenarios of population projections. They are named as High, Medium and Low variants.

The High variant represents slow decline in fertility, plausible decline in mortality and appropriate effects of migration levels which will give the higher estimates of population size. The Medium variant represents plausible decline in fertility and mortality levels along with appropriate effects of migration levels which will give the most likely estimates of population size. The Low variant represents fast decline in fertility, plausible decline in fertility and appropriate effects of migration levels which will give lower estimates of population size in years to come. In this way, population projections are made for three variants for a period of 20 years starting from 2011 at an interval of 5 years with the final year 2031.

As projections are needed by age groups and sex, the cohort-component method (Siegel 2002, p.453) is used. A computer program known as Spectrum (Future Institute, USA 1980) is used for making population projections at the national level. However, reliable data about the components of the population are not available at sub-national level. As such, the method known as Ratio/Apportionment method (Siegel 2002, P.405) is used.

2. Projections at national level

The standard method of making population projections is cohort-component or cohort-survival method. The method needs following information for June 22, 2011.

- i. Sex ratio at birth
- ii. Life tables
- iii. Adjusted base year population by age and sex
- iv. Fertility levels and trends
- v. Mortality levels and trends
- vi. Estimates of net migration to add to the survivors

The information are obtained as follows

i. Sex ratio at birth

It is found that the sex ratio at birth, number of male births per 100 female births based on census 2011 and DHS 2011 are 120.9 and 103.1 respectively. The estimates based on CEB and under one year population obtained from Census 2011 are 109.1 and 106.4 respectively.

In India, it is found that the sex ratio at birth per female is 1.11 in 2011 which is almost constant since 2001. The corresponding value was 1.07 twenty five years ago. In Singapore, the sex ratio at birth is 1.07 in 2011 and has been constant since 25 years ago. In Nepal, as the intervention is not made or negligible in the sex selection of births, it seems that the sex ratio at birth can be assumed to be 1.07 in 2011 and a little bit increasing trend in subsequent years like 1.10 in 2021 and 1.11 in 2031.

ii. Selection of the life table

The life tables are needed to get the survivors of the age-sex distribution of the population by using appropriate survival rates. The survival rates can be obtained by making life tables based on age specific mortality rates or from Model life tables. However, that life table is selected as appropriate one which gives the plausible estimate of expectation of life at birth on June22, 2011. As the plausible estimate of expectation of life at birth is obtained based on CD west model(See mortality level below), it is selected

as the suitable model life table. Moreover, when IMR is less than 50 infant deaths / thousand live births there is almost no difference between the selection of CD West model life tables or UN model life tables for developing countries (UN1990, p.10) .

iii. Adjusted base year population by age and sex

As there are age heaping in the reported population of the census, Arriaga's method (Arriaga 1992) is selected to get age adjusted population. The adjusted age distribution gives the percentage of children 0 - 14 years as 36.17% which is quite close to the reported age distribution of 36.69%. The proportion of population under age 15 years as reported by censuses are generally reliable.

iv. Estimation of fertility levels and trends

The fertility levels are estimated by Total fertility rate(TFR) which gives the total number of children a woman would have in her life time with the current age specific fertility rates. Estimates of TFR in June 2011 based on various methods and various data are shown in the following table.

Table 1: Estimates of TFR by various methods and various data

| S. No. | Methods | Data | Estimates of TFR in June 2011 |
|--------|-----------------------|-----------------|-------------------------------|
| 1. | Reported TFR | DHS 2011 @ 2006 | 2.48 |
| 2. | FERTCB(UN 1988, p.69) | DHS 2011 @ 2006 | 2.24 |
| 3. | FERTPF(UN 1988, p.73) | DHS 2011 @ 2006 | 2.48 |
| 4. | FERTCB | Census 2011 | 3.63 |
| 5. | FERTPF | Census 2011 | 2.98 |
| 6. | By definition | Census 2011 | 1.59 |

As the method FERTPF has analytical and diagnostic advantages over FERTCB when fertility is changing, this method is given more weight. The second method is based on CEB only and not on estimates of ASFR. Moreover, the estimate of 2.48 based on method 1 is almost equal to the estimate based on method 3. As such, the estimate of TFR is considered as 2.48 children/woman in June 2011.

The estimate of TFR in Nepal in 2031 is assumed to be equal to 1.8 which is more than the urban estimate of Nepal of 1.6 in and around 2009 and the estimate of Singapore of 1.5 in 2001. Assuming 1.8 as the plausible estimate of TFR in 2031, the other variants are assumed to be slightly higher and slightly lower than the plausible estimate. The higher rate is assumed to be 2.0 and the lower rate is assumed to be 1.6.

ASFR pattern in future years

The ASFR pattern in 2011 is assumed to be equal to the ASFR of DHS 2011. For 2031, ASFR pattern for younger age groups and older age groups are assumed to be lower. However, the ASFR pattern for younger age group 15-24 and older age group 45-49 increased during the period 2001 to 2011 in both DHS and census data which is contrary to the expectation. As such, the ASFR pattern for Nepal in 2031 is assumed to have ASFR distribution of Nepal of 2001 with the decrease of ASFR pattern in younger and older age groups than in 2011. Other values are linearly interpolated. The distribution of ASFR through 2011 to 2031 are shown below.

Table 2: Distribution of ASFR in 2011 and 2031.

| Age Groups | Distribution of Age Specific Fertility Rate | | | | |
|------------|---|-------|-------|-------|-------|
| | 2011 | 2016 | 2021 | 2026 | 2031 |
| 15 – 19 | 15.58 | 15.13 | 14.67 | 14.21 | 13.76 |
| 20 – 24 | 35.97 | 34.7 | 33.5 | 32.2 | 30.98 |
| 25 – 29 | 24.23 | 24.6 | 24.9 | 25.1 | 25.60 |
| 30 – 34 | 13.65 | 14.48 | 15.31 | 16.15 | 16.98 |
| 35 – 39 | 6.92 | 7.72 | 8.52 | 9.32 | 10.12 |
| 40 – 44 | 2.69 | 2.46 | 2.24 | 2.02 | 1.79 |
| 45 – 49 | .96 | .91 | .86 | .82 | .77 |

Source: Based on various DHS data and censuses

v. Estimation of mortality levels and trends

Estimation of the expectation of life at birth

The estimates of expectation of life at birth are made based on various methods and using various data. The results are shown below.

Table 3: Estimates of expectation of life at birth in 2011 by various methods

| S. No. | Methods | Data | Estimates in 2011 (Years) |
|--------|--|-----------------|---------------------------|
| 1. | Life tables (ASMR)(Siegel 2002, p.20) | Census 2011 | 72.1 |
| 2. | CEBCS(UN General Models)(UN 1988,p.47) | DHS 2011 @ 2006 | 68.8 |
| 3. | CEBCS(CD West Models) | DHS 2011 @ 2006 | 66.6 |
| 4. | Based on estimates of IMR | DHS 2011 @ 2006 | 67.7 |
| 5. | Downloaded for India | | 65.96 |
| 6. | CEBCS (CD West Models) | Census 2011 | 69.36 (2008.1) |
| 7. | CEBCS (UN General Models) | Census 2011 | 72.2 (2008.4) |

The estimate of 66.6 years given by CEBCS method based on DHS data using CD west model seems to be plausible which is slightly more than the corresponding value of India in 2011. The estimate of the expectation of life at birth was 60.39 years in Nepal compared to the corresponding value of 62.95 years in India in 2001.

It has been estimated above that the expectation of life at birth for both males and females combined is 66.6 years and the sex ratio at birth is 1.07. The census of Nepal in 2011 gives information about children ever born and still alive by sex. Now, CEBCS program is run for both females and males separately. The difference in expectation of life at birth for females and males is estimated to be 2.6 years. Using this difference of 2.6 years and sex ratio at birth 1.07, the expectation of life at birth for females and males are estimated to be 68.0 years and 65.4 years respectively.

In India, the difference in expectation of life at birth for females and males is 3.48 years in 2011 which was 2.64 in 2001 with an increase of difference of .84 years during 10 years period. With this rate, the difference will be 4.28 in 2031. In Singapore, the difference was 3.99 in 1986 when the expectation of life for females was 76.6 years. As such, the difference is assumed to be 4.0 in case of Nepal in 2031. Assuming the increase in expectation of life for females to be 1.5 years in 5 years in Nepal from 2011 onwards as estimated during the period 1986-2001 in Singapore, the trend in expectation of life at birth for females and males are shown below.

Table 4: Trend in expectation of life at birth for females and males.

| Calendar years | Expectation of life at birth for females | Expectation of life at birth for males |
|----------------|--|--|
| 2011 | 68.0 | 65.4 |
| 2016 | 69.5 | 66.6 |
| 2021 | 71.0 | 67.7 |
| 2026 | 72.5 | 68.8 |
| 2031 | 74 | 70.0 |

vi. Estimation of net migration levels and trends

Life time immigrants were estimated to be 608092 in 2001 based on foreign born population. The corresponding figure based on 2011 census is estimated to be 479625. Life time immigrants in 2011 can't be less than the corresponding figure in 2001. As such, it can be suspected that there are some problems in the estimation of immigrants. Even if the number of lifetime immigrants in 2011 is equal to the corresponding figure in 2001, the number of immigrants during the inter-censal period will be equal to zero. Hence, it can be assumed that the number of immigrants during the period 2001 to 2011 is nil or has negligible effect in the estimation of net migration.

Emigrants based on absentee population of 2011 census is estimated to be 1921494. Out of them, 1643220 people left the country during the period 2001 to 2011 while the remaining 278274 people left the country before 2001. It is assumed that a very significant proportion of 1643220 people whose duration of absence is less than ten years will return back and will have no effect in the estimation of net migration in the year 2021. On the other hand, most of the 278274 people who left the country before 2001 and whose duration of absence is more than ten years in 2011 will be emigrants in 2021 census. All the new absentee population during 2011 to 2021 will have no impact in the estimation of net migration in 2021 as their duration of absence will be less than ten years in 2021. Hence, net migration is estimated as -278274. The age and sex distribution of this population are estimated by age and sex distribution of absentee population in 2011. The trend of net migration is assumed to be constant in future years.

3. Sub-national population projections

Sub-national population projections like development regions, ecological regions or district level projections can be made by the method known as Ratio method. Cohort component method of projecting population can't be used because of the lack of reliable demographic parameters at sub-national levels. The Ratio method of Projecting population of a sub region at time t2 can be made as follows.

Steps

- i. Get the ratio of the sub-region to total population at time t0.
- ii. Get the ratio of the sub-region to total population at time t1.
- iii. Get the projected ratio at time t2 by some mathematical method.
- iv. Get the projected population at time t2.
- v. Multiply the step 3 by step 4 to get the projected population of the sub-region at time t2.

The usual procedure in getting the projected ratio at time t2 (Step 3) is to get the average annual rate of changes r_1 during the period t0 to t1 and assume the annual rate of change $r_1/2$ at time t1 which will drop to zero in 30 years. The projected ratios at time t2 are obtained by extrapolation (HMG, 2003, p12).

This method assumes that ratios in future will depend on the trend of the just past decade only but not on the trend of previous past decades. Moreover, the magnitude in the annual rate of changes are not considered but assume that rates for all sub-regions will drop to zero in 30 years. In fact, the trend of past decades and the magnitude of rates have to be considered. As such, the trend of ratios for the period 1991-2001 and 2001-2011 are considered for each sub-region and the annual rate of changes for all sub-regions are made to zero not in 30 years but at various points of time depending on the trend and magnitude of the rates.

After getting estimates of total population for all sub-regions and for various points of time, the female population and male population are obtained from the total population by using the relationship

Female population = Total population/(1+Sex ratio) , and

Male population = Total population-Female population

After getting projected total male and female for each district, the age distribution of the population by age and sex for each district are obtained according to the age distribution of the projected national population for projected years. The distribution of the population by age groups and sex for each district are obtained by making adjustments so that the total population of the district for each sex is equal to the total of the population of all age groups of the same district for the same sex and the total national population for each age group is equal to total of the same age group for all the districts in all projected years.

Projected population for development regions, ecological regions and all other regions smaller than district levels are obtained by summing over the population of the corresponding districts.

4. Projections of urban and rural population

Urban populations are affected by several factors like natural growth, large scale migration pattern and reclassification of areas. The Ratio method doesn't indicate enough how the population of an area develops . As such, projected population for urban and rural areas are obtained by a method known as Urban Rural Growth Difference (URGD) method (UN 1974, p.38).This method projects population year by year. For the population projection, urban population is defined as population residing in urban areas. The relationships used in projecting urban population for year by year is

$$U' = \left(\frac{T'+dR}{T} \right) U$$

Here, U,R and T are urban, rural and total population respectively in year t and U', R' and T' are corresponding values in year t+1; d = u - r, where u and r are urban and rural rate of increase respectively.

Hence, the total projected population for the year t+1 can be obtained if the values of U, R and T are known for the base year t and putting the value of d, the difference between urban and rural population growth rate which are obtained for the period 2001 to 2011. Age and sex distributions of urban population for future years are assumed as corresponding distributions in 2011.
